## Assignment 2: Eigenfaces for Face Recognition

### Objective:

Design a real-time face recognition system using the eigenfaces

### Understandings and Implementation Details:

- I have used *Caltech Faces* dataset of 450 images of different human beings faces and a few number of cartoon images.
- We have 450 images and each of dimension 542\* 600. We resize it into 400\*400.
- We convert it into a vector of size  $N^2$ .
- Then we calculate the mean of the face vectors and subtract it from each vectors.
- This will do with all the images and this will give a matrix of the size of  $N^2 \times M$ .
- Then find the Covariance matrix by the multiplication of A and  $A^T$ . Dimension of A is  $N^2 \times M$ .

$$Cov = A^T \times A$$

The dimension of covariance matrix is  $M \times M$ . Here M is number of images and it is computationally efficient.

- After computing the covariance matrix, we calculate the eigenvalues and eigenvectors using the formula:

$$A^T A v_i = \lambda_i v_i$$

$$A A^T A v_i = \lambda_i A v_i$$

$$C' u_i = \lambda_i u_i \quad \text{where } C' = A A^T \text{ and } u_i = A v_i$$

- Here  $C'$  and  $C$  have same eigenvalues and eigen vector.  $C = A^T A$
- First we calculate eigenvectors and eigenvalues of C and map them to  $C'$  using the formula  $u_i = A v_i$ .
- Corresponding to the K largest eigenvalues of  $C'$  we select the K eigenvectors and K should be less than M.

- Thereafter take the normalized training faces.
- Then represent each face vector in the linear combination of K eigenvectors

$$\text{Formula: } x_i - \psi = \sum_{j=1}^k w_j u_j \text{ where } u_j \text{ are the eigenFaces}$$

- Take the coefficient of eigenfaces and represent the training faces in form of a vector.

### Testing

- In the testing implementation, I separated 45 images from the given dataset.
- The first process is preprocessing the data.
- Each face vector is subtracted from the test face from mean values.
- We normalize the vector and project into eigenspace to get eigenfaces.

$$\phi = \sum_{i=1}^k w_i u_i$$

- We take the vector of coefficients and subtract it from training image to get the least distance between train image and test image.
- Using this distance we plot the %error vs k graph.

### Results:

#### Mean Face:

```

## Accuracy:

The graph will show the accuracy of the test model under different K values with a certain threshold.

## Percentage error vs K (K number of eigenvectors) graph:

We set the threshold of 20 that if the distance is greater than 20 then it is not correctly detected. From this, we get the result of the above graph.

## Inferences from the Result:

1. We can further decrease the result through increase the dataset
2. We can use the Convolutional Neural Network model to build a better Face Recognition System.
3. From the above accuracy graph, we get the insight that on increasing the K values the % error is decreasing but after 23 it seems to saturate to 40% with a threshold 20.
